

Transplant Candidates Seek Quality Despite Remaining On Waiting List

New research reveals that liver transplantation candidates want to be involved in decisions regarding quality of the donor organ, and many are reluctant to accept organs with a higher risk of failure. In fact, more than 42 percent of patients would choose to remain on the waiting list rather than accept a "lower quality" liver according to the study appearing in the December issue of *Liver Transplantation*, a journal published by Wiley-Blackwell on behalf of the American Association for the Study of Liver Diseases.

As of November 30, 2011, the Organ Procurement and Transplantation Network (OPTN) reports that 16,124 candidates are on the waiting list to receive a liver, with only 5,375 deceased donor organs recovered through August. Additionally, there is a large variation in quality of deceased donor livers, which is based on donor characteristics such as age, cause of death, and ischemia time. Previous research has shown that donor characteristics can make the difference between a 20 to 40 percent risk of graft failure by three years following transplantation.

"Organ quality is an important issue for all liver transplant candidates, increasingly so, given the aging donor pool and more frequent use of organs that carry a higher risk of failure," explains Dr. Michael Volk with the University of Michigan Health System in Ann Arbor. "The decision to accept or pass on an organ could mean the difference between life and death for patients with end-stage liver disease. Communication of the risks versus benefits of accepting a "lower quality" organ is critical, and understanding patient views on the subject is essential for physicians caring for transplant candidates."

Findings show that patients are reluctant to accept higher risk organs, wanting only the "best" organ. Of those completing the survey, 58 percent would only accept organs with a 25 percent (or less) risk of graft failure and 18 percent would only accept the lowest possible risk of 19 percent at three years following transplantation. Women were slightly more accepting of high risk organs than men. Researchers found that risk tolerance was increased by presenting organ quality as "average quality" rather than "best quality," and by providing feedback about the implications of these preferences on the likelihood of receiving a transplant. Additionally, 83 percent of candidates were found to prefer an equal or dominant role in deciding whether to accept a higher risk organ. This finding is striking given that, in most transplant centers, patient involvement in these decisions is minimal.

"Up until now, it has not been clear how much patients want to be involved in this complicated decision," says Dr. Volk. "Furthermore, explaining the intricacies of this topic to sick patients is easier said than done. Our findings offer transplant physicians some useful guidelines for how to counsel transplant candidates on

issues of organ quality." The authors suggest future studies are needed to develop validated patient education tools that will enhance discussions between physicians and patients in need of liver transplantations.
